18 **Abstract**

19 To improve the early perinatal conditions of broiler chicks, alternative hatching systems
20 have been developed. On-farm hatching (OFH) with an enriched microbial and
21 stimulating environment by the presence of an adult hen is a promising solution. Day-
22 old chicks were allotted within five hatching and rearing conditions: OFH, conventional
23 hatchery (CH), CH and post-hatching treatment with antibiotics (CH + AB), as well as
24 both hatching systems with an adult hen at hatching (OFH + H, CH + H). To challenge

29 the robustness of chickens, they were exposed on D27 to suboptimal rearing
30 conditions, by combining for 4 h transport in boxes in a new room at a lower temperature
31 and fasting. On their return to the original room, the chicken density was increased,
32 and birds were orally vaccinated with the Gumboro vaccine. The impacts of these
33 conditions on hatchability, chick quality score, performance, health and robustness
34 were determined. The OFH chick body weights (BW) were significantly greater than
35 those of CH chicks at hatching. Whereas there was no effect of hatching conditions,
36 the presence of hens decreased the hatchability rate, the quality score of OFH chicks
37 and increased mortality at hatching. Treatment of CH chicks with antibiotics (CH + AB)
38 temporarily decreased chicken BW at D19, but the feed conversion ratio (FCR) was
39 not modified. At D19, OFH chicks had the highest BW compared to the other groups,
40 and the presence of hens at hatching harmed chicken BW regardless of the hatching
41 condition and FCR. An interaction between the effect of experimental rearing
42 conditions and chicken sex was observed later for BW. In males, the OFH chickens
43 were the heaviest compared to the other groups at D34 but not at D56. The presence
44 of hens negatively impacted CH chicken BW at D56. In females, there was no effect
45 of hatching condition on the BWs at D34 and D56, and the presence of hens had a
46 positive impact on OFH chicken BW. There was no effect of hatching conditions on
47 health parameters. In conclusion, the OFH system was a hatching system at least
48 equivalent to the CH system. The presence of the hen at hatching and during the chick
49 start-up phase on performance interacted with the hatching condition and the sex of
50 the chickens.

68 **Introduction**

69 The integrated management of poultry health includes maintaining health, welfare and
70 performance throughout the life of animals. This is an even greater challenge in a
71 global context of reducing the risk of antimicrobial resistance. One axis in the
72 Ecoantibio2017 plan (Ecoantibio2, 2017) concerns the development of alternatives to
73 avoid the use of antibiotics. In this context, new poultry rearing systems are being
74 developed, particularly for the perinatal period. In poultry, the perinatal period is a
75 stressful period for broiler chicks, which includes the hatching phase and major
76 physiological changes to adapt to new food resources and environments. In
77 hatcheries, chicks hatch between 19 and 21 days of incubation. They often stay more
78 than 12 hours in the hatcher, under optimal temperature, without light and usually
79 without access to feed and water until placement in farm buildings. The fasting period
80 of the chicks is further increased by the time needed for hatchery processing,
81 transportation duration and unloading at the farm, which might last up to the first 72 h
82 after hatching. Even though chicks can use energy reserves from their yolk sac (van
83 der Wagt et al., 2020), these conditions induce immediate and long-lasting metabolic
84 changes (Beauclercq et al., 2019; Foury et al., 2020), behavioural impacts by
85 increasing fear responses (Jessen et al., 2021) and consequences on chicken
86 development, performance and welfare (de Jong et al., 2017).

87 To improve the early perinatal conditions of chicks, alternative hatching systems have
88 been developed. On-farm hatching provides the chicks with immediate access to feed
89 and water according to their needs and avoids the exposure to stressors encountered
90 in conventional hatcheries (van de Ven et al., 2009). Eggs incubated for 18 days are

a supprimé: ¶

a mis en forme : Titre 1, Gauche

a supprimé: overall

a supprimé: at

94 transported to the farm and placed either in trays or in the litter where they hatch. The
95 effects of these on-farm hatching systems on broiler health, welfare and performance
96 were recently studied under commercial or more controlled conditions and had shown
97 effects that are not always beneficial. Total mortality and footpad dermatitis in on-farm
98 hatched (OFH) chicks were lower compared to conventionally hatched (CH) fast-
99 growing broiler chickens (de Jong et al., 2019; 2020; Giersberg et al., 2021; Jessen et
100 al., 2021). However, day-old chick quality was worse and breast myopathy prevalence
101 was higher for OFH than CH chickens (de Jong et al., 2019; Souza da Silva et al.,
102 2021).

103 Chicken activity and general behaviour were little affected by the hatching system, with
104 fast-growing OFH chickens being more fearful and less active than CH chickens
105 (Giersberg et al., 2020). Slower-growing broiler chickens hatched in organic farms
106 tended to express less general fearfulness than CH chickens (Jessen et al., 2021a). A
107 positive effect on growth performance was observed during the first week of life until
108 21 days in OFH and CH fed at the hatchery compared to CH chickens (de Jong et al.,
109 2020), and longer when parent flocks were young (Souza da Silva et al., 2021).

110 Maintaining optimal health, welfare and performance of chickens is highly dependent
111 on the gut physiology in interaction with the microbiota and mucosal immune system
112 (Fortun-Lamothe et al., 2023). Antibiotics have been largely used in poultry production

113 to improve performance, Growth promotion induced by antibiotics is associated with
114 effects on the caecal microbiome at taxonomic, metagenomic, and metabolomic levels,
115 which might be targeted via its contribution to host-microbiota crosstalk, particularly by
116 acting on the gut barrier function (Broom, 2018; Plata et al, 2022). However, growing
117 concerns about the increase of antimicrobial resistance in farm animals led to changes

a supprimé: by acting on the gut barrier function (Broom, 2018)...

120 in EU and national legislation governing the use of antibiotics as growth promoters in
121 poultry feed, which resulted in their suppression in 2006 (Council Directive 96/22/EC;
122 Axis 2 and measure 19 of the EcoAntibio2017 plan).

123 Greater attention to the environment during the chick postnatal period, especially the
124 microbial environment, is key to optimising the gut barrier function and more broadly
125 the health and welfare of the chickens and their performance. Naturally, chicks hatch
126 in contact with an adult hen who is a donor of microbiota and a model of learning and
127 maternal care (Edgar et al., 2016). Early implantation of adult microbiota into the chick
128 digestive system accelerates the maturation of the microbiota and immune system
129 (Volf et al., 2016; Broom & Kogut, 2018; Meijerink et al., 2020). In addition, chicks
130 reared in the presence of their mothers are less fearful than those raised without their
131 mothers and develop more behavioural synchrony (Perré et al., 2002), even though
132 hen genetics has a strong effect on chick behaviour, with commercial lines being less
133 maternal (Hewlett et al., 2019). The combination of a new hatching system like OFH
134 with an enriched microbiota and stimulating environment from the presence of an adult
135 hen is a possible solution for chick conditions to be improved and could contribute to
136 poultry health and welfare and product quality.

137 In this study, we analysed the benefits/risks of hatching systems (conventional hatcher,
138 on-farm hatching), with the presence of an adult hen (OFH + H, CH + H) or not (OFH
139 and CH) on hatchability and chick quality scores. We also explored the effects of these
140 hatching conditions and the presence of an adult hen with chicks on performance,
141 health and robustness in suboptimal rearing conditions. The combination of CH and
142 post-hatching treatment with antibiotics, (CH + AB) was added as an experimental
143 control group of antibiotic growth promoter use.

The hens were aged 31 weeks, vaccinated against Marek Disease Virus (MDV), Infectious Bursite Disease Virus (IBDV) and Infectious Bronchitis Virus (IBV) infections, and were sanitary controlled and declared free of *Mycoplasma gallisepticum*, *Mycoplasma synoviae*, *Chlamydia psittaci* and *Salmonella pullorum*. Only *Ascaris* and *Heterakis* parasites were detected in hen faeces, and they were at a very low level.¶ Each hen was placed separately in a wire-latticed pen (3 m²) in the experimental pens described above with a nest box, perch, feed and water ad libitum. Hens were accustomed to their new environment for 12 days, fed with a standard rearing diet for laying hens (30099G25, Arrivé Nutrition Animale, Saint-Fulgent, France) and allowed to deposit faecal and caecal microbiota on litter. The room temperature was 25 °C and the artificial photoperiod was 16 h L:8 h D before egg deposition, 20 h L:4 h D during hatching and the same programme as the chicks afterwards. Two days before chick arrival or egg hatching, a wire-latticed space for chicks was placed in their pen. Eight hens were used for 8 groups of 18 OFH chicks, and eight hens were used for 8 groups of 18 CH chicks. On D0, day-old CH chicks were placed under the pen's wire-latticed space, and OFH chicks were already under this space. Chicks and hens were in visual and auditory contact for a few hours. Then hens were deprived of feed and water from the morning. When lights were switched off, the hens were shut up in their nest boxes, and chicks were placed under each hen as gently as possible for 11 h without any feed and water. Chicks and hens were put physically together in a closed nest for the night to promote maternal behaviour and the acceptance of chicks (Richard-Yris & Leboucher, 1987). The following morning, one hour before the lights were switched on, the nest-box doors were taken away to allow free access to the whole pen. Free in-access feed and water were placed under wire-latticed space for chicks and in raised troughs for hens, not accessible for chicks. Hens were present with chicks for two weeks, the critical period for chick start, and removed on D15. Weight and clinical examinations of the hens were recorded the day before they were installed in the pens and, on D15, when they were removed.¶

251 *gallinarum*. Only *Ascaris* and *Heterakis* parasites were detected at a very low level in
252 hen faeces.

253 Each hen was placed separately in a wire-latticed pen (3 m²) in the experimental pens
254 described above with a nest box, perch, feed and water *ad libitum* (Figure 2A). Hens
255 were accustomed to their new environment for 12 days, fed with a standard rearing
256 diet for laying hens (30099G25, Arrivé Nutrition Animale, Saint-Fulgent, France) and
257 allowed to deposit faecal and caecal materials and thus microbiota on litter. An egg
258 was always left in the nest to encourage brooding behaviour. The room temperature
259 was 25 °C and the artificial photoperiod was 16 h L:8 h D before egg deposition, 20 h
260 L:4 h D during hatching and the same programme as the chicks afterwards. Two days
261 before chick arrival or egg hatching, a wire-latticed space (101 x 50 cm) for chicks was
262 placed in their pen (Figure 2B). Eighteen-day embryonated eggs were laid under
263 infrared heat lamps to allow on-farm hatching (OFH) (Figure 2C). Eight hens were used
264 for 8 groups of 18 OFH chicks, and eight hens were used for 8 groups of 18 CH chicks.
265 On D0, day-old CH chicks were placed under the pen's wire-latticed space, and OFH
266 chicks were already under this space. Chicks and hens were in visual and auditory
267 contact for a few hours. Then hens were deprived of feed and water from the morning.
268 When lights were switched off, the hens were shut up in their nest boxes, and chicks
269 were placed under each hen as gently as possible for 11 h without any feed and water.
270 Chicks and hens were put physically together in the closed nest for the night to promote
271 maternal behaviour and the acceptance of chicks (Richard-Yris & Leboucher, 1987).
272 The nest was made of wire mesh covered with a tarpaulin and placed on shavings.
273 The following morning, one hour before the lights were switched on, the nest-box
274 tarpaulins were taken away to allow free access to the whole pen. The nest was

292 Seven hundred twenty-day-old among which 432 were from a conventional hatchery
293 (CH) and 288 were hatched on-farm (OFH), were allocated into five groups: CH, CH +
294 antibiotics treatment (CH + AB), CH + hen (CH + H), OFH, OFH + hen (OFH + H)
295 (Figure 1). Each group was randomly placed in the room, repeated in eight pens (18
296 chicks/pen, 3 m²). Antibiotic treatment was only applied in chick drinking water for the
297 CH + AB group: ADJUSOL[®] TMP SULF Liquid (25 mg/kg sulfadiazine and 5 mg/kg
298 trimethoprim, VIRBAC, CARROS, France) for 5 days (D2–D6) and SURAMOX 50 (400
299 mg/10 kg, i.e. 20 mg/kg amoxicillin, VIRBAC) for 5 days (D19–D23). Sex was
300 determined on D19, and the number of chickens was adjusted to a maximum of 16 per
301 pen, keeping a balanced ratio between males and females. On D27, chickens were
302 exposed for 4h, transport in boxes to a new room at a lower temperature (15 °C instead
303 of 25 °C) and feed deprivation. On their return to the original room, the pen size was
304 reduced from 3 m² to 1.5 m² to increase chicken density, and birds were orally
305 vaccinated with the live Gumboro vaccine in drinking water (HIPRAGUMBORO[®] - G97,
306 HIPRA FRANCE, Saint-Herblain, France). These conditions are stress factors that
307 chickens may encounter on farms; the objective was to expose chickens to suboptimal

a supprimé: on tagged chickens on D19,

a supprimé: challenged

a supprimé: by combining

a supprimé: 4 h of

a supprimé: during rearing

315 rearing conditions. Chickens had ad libitum access to water and to feed without any
316 anticoccidial drugs. They were fed with a standard starter diet (raw energy = 4462
317 kcal/kg, crude protein = 23.91%) until D19, then a grower diet from D20 to D34 (4527
318 kcal/kg, crude protein = 20.51%) and a finisher diet from D35 to D56 (4600 kcal/kg,
319 crude protein = 19.98%). A wire mesh platform and a perch were used for
320 environmental enrichment.

322 Chick quality scores

323 Chick quality scores were determined at placement in the pen for CH chicks (D0),
324 corresponding to 21 days of incubation for OFH chicks, on 24 to 25 chicks from the
325 three treatments: CH (at the entrance into the pens), OFH and OFH + H (after hatching
326 within their pen). They were macroscopically defined according to the grid of Tona
327 (Tona et al., 2003) and modified by adding several other parameters (Guinebretière et
328 al., 2022). Briefly, the chicks were scored on a total score of 110, including scores of
329 posture (on 5), down (on 5), legs (on 6), red dot on the beak (on 10), grouped into an
330 “appearance” score (on 26); activity (on 6), eyes (on 16), leg joint inflammation (on 5)
331 and leg dehydration (on 5) were grouped into a “tiredness” score (32), and finally,
332 retracted yolk (on 12), navel (on 12), remaining membrane (on 12), and remaining yolk
333 (on 16) were grouped in an “abdomen” score (on 52).

483 The scan sampling method was used to follow the behaviour of hens and chicks on
484 days 2, 5, 6, 7, 8, 9, 12, 13 and 14 with the following repertoire: resting (the hen is lying
485 or standing still, eyes closed and without chicks), maintenance (preening, scratching,
486 stretching), feeding behaviour (the hen is eating or drinking), locomotion, exploration
487 (the hen is scratching or pecking at the ground or the environment), observation (the
488 hen is observing the environment with neck movements), maternal behaviour (the hen
489 is making food offering to the chicks, the hen is expressing maternal calls, the hen is
490 brooding the chicks by lying down and spreading her wings), fear behaviour (the hen
491 is flying or running from the experimenter, freezing, alert), agonistic behaviour (the hen
492 is chasing the chicks, the hen is pecking the chicks, others (punctual behaviours like
493 vocalisations). To characterise hens' behaviour towards the chicks, each hen was
494 categorised according to the frequencies of agonistic or maternal behaviours. We
495 defined three categories: 1) maternal (M): the hens expressed only maternal
496 behaviours towards the chicks; 2) tolerant (T): the hens expressed both maternal and
497 agonistic behaviours towards the chicks or less than 5% of scans with maternal
498 behaviour; 3) aggressive (A): the hens rejected the chicks and expressed only
499 agonistic behaviour towards them.
500 To evaluate the proximity between chicks and hens, the experimenter also recorded
501 the localisation of four chicks randomly tagged at D0 per pen and the hen within the
502 pen. To that end, the pen was virtually divided into four zones (Figure 3). The
503 observations were conducted between 10 AM and noon and between 3 and 5 PM by
504 the same experimenter. The experimenter walked slowly in front of each pen and
505 recorded the behaviour of the hen and the localisation of the four tagged chicks every

 519 four tagged chicks and the hen during behavioural observations; A: the nest (23 cm
 520 wide x 35 cm long x 40 cm high), B and D: two halves of the pen and C: the wire-
 521 latticed space for the chicks (101 × 50 cm).

522
 523 **Performance**

524 Body weight (BW) was measured at D₀, D₁₉, D₃₄ and D₅₅. Feed consumption was
 525 measured in each pen for the periods between D₀-D₁₉, D₁₉-D₃₄ and D₃₄-D₅₅, and
 526 then used to calculate the feed conversion ratio (FCR) as the feed consumption-to-BW

a supprimé: 1

a déplacé vers le bas [2]: Health parameters
 Droppings deposited on pen litter were collected on D14 and D54 and analysed for parasite detection (*Coccidia*, *Ascaris* and *Heterakis*). Five grams of droppings were homogenised in 70 mL of flotation solution (0.36% of sodium chloride). The mixture was then filtered and pressed through a tea strainer (small mesh) to extract as much of the liquid part as possible. A homogeneous sample was deposited into a McMaster cell counter, and after 5 min of rest, the oocysts and nematode eggs were counted, and their number was expressed per gram of droppings (OPG). Health disorders, mortality and causes of death were registered during the experiment.

a supprimé: 1

Chick quality scores
 Chick quality scores were determined at placement in the pen for CH chicks, corresponding to 21 days of incubation for OFH chicks, on 24 to 25 chicks from the three treatments: CH, OFH and OFH + H. They were macroscopically defined according to the grid of Tona (Tona et al., 2003) and modified by adding several other parameters issued from the CASDAR QUALICOUV project (Guinebretière et al., 2022). Briefly, the chicks were scored on a total score of 110, including scores of posture (on 5), down (on 5), legs (on 6), red dot on the beak (on 10), grouped into an "appearance" score (on 26); activity (on 6), eyes (on 16), leg joint inflammation (on 5) and leg dehydration (on 5) were grouped into a "tiredness" score (32), and finally, retracted yolk (on 12), navel (on 12), remaining membrane (on 12), and remaining yolk (on 16) were grouped in an "abdomen" score (on 52).

a supprimé: 1

a supprimé: 1

563 gain ratio per pen during both periods and the entire rearing period. At D56, 16
564 identified males per group were slaughtered, and *pectoralis major* and *pectoralis minor*
565 (breast) muscles were weighed to calculate their yields relative to BW and ultimate pH.
566 Ultimate pH was measured as the pectoralis major pH 24 hours after slaughter.

567 Health parameters

568 Droppings deposited on pen litter were collected on D14 and D54 and analysed for
569 parasite detection (*Coccidia*, *Ascaris* and *Heterakis*). Five grams of droppings were
570 homogenised in 70 mL of flotation solution (0.36% of sodium chloride). The mixture
571 was then filtered and pressed through a tea strainer (small mesh) to extract as much
572 of the liquid part as possible. A homogeneous sample was deposited into a McMaster
573 cell counter, and after 5 min of rest, the oocysts and nematode eggs were counted,
574 and their number was expressed per gram of droppings (OPG). Health disorders,
575 mortality and causes of death were registered during the experiment.

577 **Statistical analyses**

578 Hatching rates between hatchery and on-farm hatchings were compared using chi-
579 squared tests. Chick quality parameters were analysed by a non-parametric Kruskal-
580 Wallis test, considering the treatment (CH, OFH and OFH + H), followed by Mann-
581 Whitney post hoc tests. A 2-way ANOVA was then carried out to test the effects of the
582 experimental group, the sex and their interaction on performance. The statistical model
583 used was then: $Y_{ij} = \mu + a_i + b_j + ab_{ij} + e_{ij}$ where Y_{ij} is the dependent variable, μ the
584 overall mean, a_i the Experimental group (CH, CH + AB, CH + H, OFH, OFH + H), b_j

595 was an interaction between variables, a Fisher (LSD) test was used to determine the
596 statistical significance of the difference. Differences were considered significant when
597 p-values < 0.05 and a tendency for 0.05 < p < 0.1. Analyses were performed using
598 XLSTAT software (version 2015, Addinsoft, Paris, France).

a supprimé: 1

a supprimé: 05

599 Behavioural data did not meet the assumption of normality and homogeneity of
600 variances. Non-parametric Mann-Whitney U-tests were used on the mean percentage
601 of scans per behavioural category to compare the behaviour of hens in contact with
602 CH chicks to the hens in contact with OFH chicks. To compare the proximity of CH and
603 OFH chicks towards the hen, Mann-Whitney U tests were conducted on the mean
604 number of tagged chicks located in the same area of the pen as the hen over the 177
605 scans recorded per hen.

606

607 Results

608 Hatchability and chick quality

a déplacé (et inséré) [3]

609 Hatchability

610 For conventional hatchers, 97.7% of CH fertile eggs hatched at E21 and 97.2% ± 4.2%
611 of OFH fertile eggs hatched at E21 in pens. The presence of hens had a significant
612 impact on the OFH condition (p = 0.034). In the presence of hens, 86.8% ± 11.9% of
613 OFH + H chicks hatched at E21. Unhatched eggs were mainly found in the pens with
614 aggressive hens (9/11) or in the OFH pens next to those with aggressive hens (4/4).
615 No mortality of CH chicks or OFH chicks was observed at hatching, whereas 5.6% ±

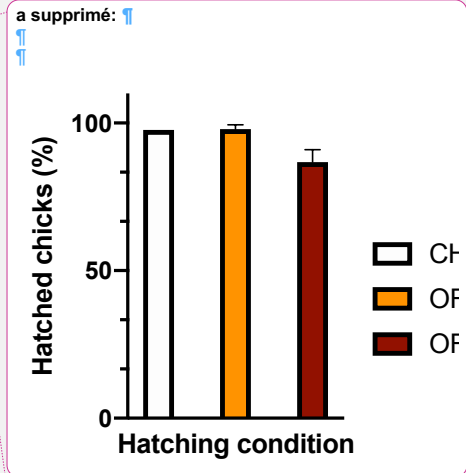

a supprimé: (Figure 3)

619 5.9% (from 0 to 16.7% according to the pen) OFH + H chicks died or were removed at
 620 hatching (n = 10) due to three hens' aggressiveness or another reason. Only 3.6%
 621 (2/56) of chicks had residual yolk sacs at the age of 20 days (one CH and one CH +
 622 AB) and no yolk residue was found at 56 days.

a supprimé: ;

623 Quality scores of chicks

624 No difference was shown due to the hatching conditions ($p > 0.05$) on the total quality
 625 scores, with good scores in the three groups considered (OFH: 96.2 ± 1.5 , CH: $97.3 \pm$
 626 1.5 ; CH+H: 95.1 ± 1.7). However, the subtotal score of the appearance was impacted
 627 by treatment whereas the subtotal scores for tiredness and abdomens of the chicks
 628 were unaffected by treatment ($p > 0.05$, data not shown). Indeed, whereas the subtotal
 629 score for appearance was not different between CH chicks or OFH chicks, it was
 630 deteriorated by the presence of the hen within the hatching pen in OFH + H compared
 631 to OFH chicks ($p = 0.01$) (Figure 4).

a supprimé: Figure 3. Number of live hatched chicks according to hatching conditions; conventional hatchery (CH) condition performed in one hatchery (one value); on-farm hatching (OFH) and on-farm hatching with hen (OFH + Hen) conditions were repeated in eight pens each, each pen contained 18 embryonated eggs or chicks; values are expressed as means ± standard error

666 **Behavioural observations**

667 Because 3 hens (1 OFH + H and 2 CH + H) were very aggressive and injured their
 668 chicks, they were removed from the pens (the following day after the overnight physical
 669 contact with chicks, when they had access to the whole pen even if the chicks had
 670 access to their own space) and the later behavioural analysis. However, the chicks
 671 were kept in the analysis as they were in contact with their hen during hatching and
 672 with the microbiota the hen deposited in the pen. There was no significant difference
 673 in the behaviour of the hens, regardless of the hatching condition of chicks, except for

675 the frequency of the behaviour "observe"; OFH hens tended to observe their
 676 environment less than CH hens ([Additional file: Table S1](#)).

a déplacé vers le haut [4]: To characterise hens' behaviour towards the chicks, each hen was categorised according to the frequencies of agonistic or maternal behaviours (Table 2). We defined three categories: 1) maternal (M): the hens expressed only maternal behaviours towards the chicks; 2) tolerant (T): the hens expressed both maternal and agonistic behaviours towards the chicks or less than 2% of scans with maternal behaviour; 3) aggressive (A): the hens rejected the chicks and expressed only agonistic behaviour towards them. Two hens were defined as maternal, six were tolerant, and five were aggressive among the 13 hens analysed (Table 2).

a supprimé: Table 2. Classification of hen according to the frequencies ... [3]

a supprimé:

a supprimé:

a supprimé: . (Figure 2)

a supprimé:

Figure 2. Proximity between chicks and hens according to hatching conditions; four chicks were observed per pen ($n \leq 8$ scans per day) per hatching condition (conventional hatchery, CH or on-farm hatchery, OFH)

726 **Performance**

727 Hatching conditions significantly influenced chick BW from hatching to slaughter age.
728 The OFH chick BW was significantly greater than that of all CH chicks at hatching,
729 whether hens were present or not ($p \leq 0.002$, Figure 5). A sex effect was observed
730 from D19 onwards; male chicken BWs were greater than those of females (males: 503
731 ± 46 g, females: 469 ± 37 g, $p = 0.0001$). Treatment of CH chicks with antibiotics
732 temporarily decreased chicken BW at D19 ($p = 0.035$) (Figure 5) due to a decrease in
733 weight gain in females (Table 2) compared to CH chickens, while feed intake (data not
734 shown) and FCR were not different (Table 2). At D19, OFH chickens had the best BW
735 compared to all other groups of chicks ($p \leq 0.0003$) (Figure 5) and the best weight
736 gained per chicken (Table 2). At this time, the presence of hens at hatching with CH
737 and OFH chicks had a remnant negative impact on chicken BW regardless of the
738 hatching condition ($p < 0.0001$), as well as on weight gain and FCR for the period D1-
739 D19 (Table 2). Both the feed intake per chicken (CH: 624 ± 12 g^a, CH + AB: $600 \pm$
740 27 g^{ab}, CH + H: 603 ± 25 g^{bc}, OFH: 652 ± 33 ^a, OFH + H: 615 ± 34 ^c, $p = 0.001$) and the
741 weight gained per chicken (Table 2) decreased compared to the other groups, and the
742 FCR increased (Table 2). An interaction between the effect of the experimental group
743 and chicken sex on BW was observed later at D34 ($p = 0.012$) and D56 ($p = 0.022$) on
744 BW, even though the FCR was not affected (Table 2). At D34, a week after the
745 challenge, the OFH male chickens were the heaviest compared to the other groups (p
746 ≤ 0.033) and the best weight gain (Table 2). The presence of hens at hatching harmed
747 chicken BW ($p \leq 0.0004$), regardless of the hatching condition (Figure 6A) and the FCR
748 was not affected (Table 2). In females, there was no effect of hatching condition or

a déplacé vers le haut [3]: Hatchability and chick quality

Hatchability

For conventional hatchers, 97.7% of CH fertile eggs hatched at E21 and 97.2% \pm 4.2% of OFH fertile eggs hatched at E21 in pens. The presence of hens had a significant impact on the OFH condition ($p = 0.034$). In the presence of hens, 86.8% \pm 11.9% of OFH + H chicks hatched at E21 (Figure 3). Unhatched eggs were mainly found in the pens with aggressive hens (9/11) or in the OFH pens next to those with aggressive hens (4/4). No mortality of CH chicks or OFH chicks was observed at hatching, whereas 5.6% \pm 5.9% OFH + H chicks died or were removed at hatching ($n = 10$); due to three hens' aggressiveness or another reason. Only 3.6% (2/56) of chicks had residual yolk sacs at the age of 20 days (one CH and one CH + AB) and no yolk residue was found at 56 days.

828 presence of hens on the BW at D34 (Figure 6A). At slaughter age (D56), there was no
829 effect of hatching condition on the male chicken BW, but the presence of hens at
830 hatching harmed CH chicken BW ($p = 0.0008$) (Figure 6B) and weight gain for the
831 period D34 – D56 (Table 2). There was a pen effect in CH + H ($p = 0.016$) and OFH +
832 H chickens ($p = 0.001$), the pen with the lightest CH + H males was in the presence of
833 an aggressive hen, and the heaviest OFH + H males were in a pen in the presence of
834 a tolerant hen, but all combinations were observed (Additional file: Figure S1). In
835 females, there was no effect of the hatching condition on the BW. The presence of
836 hens at hatching had a positive impact on OFH female chickens compared to CH
837 female chicken BW ($p = 0.0096$), with the OFH + H chickens being the heaviest
838 compared to the other CH female conditions (Figure 6B) and having the best weight
839 gain for the period D34 – D56 (Table 2). There was no significant pen effect between
840 CH + H and OFH + H female chickens ($p = 0.447$).

888 Health and robustness

889 *Coccidia* was detected in variable amounts in the droppings of all the pens at D54
890 (200–85500 OPG) without any significant effect of the hatching conditions in the
891 presence of hen or not ($p = 0.606$). No clinical signs were observed during the
892 experiment. In all hatching conditions combined, the viability rate of the chickens was
893 95.3%. The mortality rate during the whole experiment was 3.19% (23/720). Seventeen

895 chicks died during the first week of life, 11 OFH + H and 5 CH + H in the presence of
896 hens and one OFH chick for an unknown reason. Six CH chickens died during the rest
897 of the experiment, five of which were due to heart problems (2 CH, 1 CH + AB, 2 CH
898 + H) and one to unknown causes (CH + H). Eleven chicks were additionally eliminated
899 after hatching in pens in the presence of hens (4 at D1, 4 at D2, and 1 at D4) and two
900 later (D33 and D55) for morphological reasons.

901

902 Discussion

903 New hatching systems are being developed in Europe, and the enrichment of the
904 rearing environment is also in full development, notably by optimising the microbial
905 environment of the chicks to limit the use of antibiotics. In this study, we analysed the
906 benefits/risks of hatching systems (OFH and CH, treated with antibiotics or not) and of
907 the presence of an adult hen or not on hatchability, chick quality score, performance,
908 health and robustness.

909 Hatching conditions

910 The hatching conditions compared within the present study concerned a combination
911 of environmental parameters diverging for both hatching conditions (hatcher or on-
912 farm), from the light regimen to the hatching temperature and the relative humidity, and
913 the egg position. Additionally, there was a partial contact with the litter through the
914 floor-hatching device compared to the hatcher crate. The BW of OFH-certified JA757
915 chicks was significantly greater than that of CH chicks at hatching, even though the
916 hatchability rate and the quality score of chicks were comparable between the two
917 conditions, and no mortality was reported. These results agree with other studies

a mis en forme : Non Surlignage

a mis en forme : Normal (Web)

918 performed on larger number of fast-growing broilers in terms of BW, but not in terms
919 of chick quality, which was lower in OFH chicks than in CH chicks (de Jong et al., 2020;
920 Souza da Silva et al., 2021). In OFH-slow-growing organic broilers, BW was also
921 reported greater, as well as the hatchability, and of lesser chick quality than that of CH
922 chicks at hatching (Jessen et al., 2021a; Jessen et al., 2021b). However, in our study,
923 there was no effect of hatching conditions, but the presence of hens decreased the
924 hatchability rate, the appearance quality score of OFH chicks and increased mortality
925 at hatching. The negative effect on these indicators could be linked to the very few
926 hens expressing a clear maternal behaviour towards the chicks (n = 2/16); some of
927 them even showed agonistic behaviour. However, this genetic line was chosen
928 because the studied practice could favour the possibility to use culled hens in breeding,
929 and because of their rather tolerant behaviour, it may be possible to optimize their
930 brooding behaviour. Improvements could be obtained by carrying it out in a season
931 with days with greater light amplitudes (spring) to facilitate brooding behaviour, which
932 was not the case in this study (winter), and by selecting hens with brooding behaviour
933 to facilitate maternal behaviour (Shimmura et al., 2010). Light color and intensity are
934 also known to influence social interaction between hens, and tuning both the color and
935 the intensity could be a management strategy to decrease aggressive behaviour such
936 as pecking but whose effects vary according to age, genetics and activities (Du et al.,
937 2022). In addition, in our experimental design, the chicks had to feed under the wire-
938 lattice space, which was not accessible to the hen. As they obtained both food and
939 warmth under this space, the hens probably did not have enough tactile stimulation
940 from the chicks to fully express their maternal behaviour with no agonistic behaviour.
941 Indeed, in addition to the physiological state, tactile stimulations from chicks play an

a supprimé: ¶

962 **Starting period**

963 Hatching conditions and the presence of hens for 15 days after placement significantly
964 influenced chick performance during the starting period. At D19, OFH chicks had the

965 highest BW compared to the other groups. No significant differences were observed in

a supprimé: best

966 the behaviour of hens present with OFH and CH chicks, except for OFH hens, which
967 were found to observe their environment less than CH hens. With our small sample
968 size, this result could be explained by the behaviour of one OFH hen, which spent
969 much of the time resting. The CH and OFH chicks did not differ in their proximity
970 towards the hen. The mean number of chicks observed in the same area as the hen
971 was very low (less than 1 chick), indicating that they were rarely in contact with the
972 hen. However, chick performance was affected by the presence of the hens, including
973 lower feed intake and consequently lower weight gain and higher FCR. This could be
974 explained by the agonistic behaviour of some hens towards chicks, the attempt of the
975 hens to eat the chick feed and the stress that this may have caused the chicks.

a supprimé: and the presence of hens at hatching
harmed chicken BW regardless of the hatching
condition and on FCR. ...

976 Treatment of CH chicks with antibiotics, assessed as growth promoters, temporarily
977 decreased chicken BW at D19, but FCR was not modified. This effect was not
978 observed later, but growth promotion was not observed in CH chicks treated with
979 antibiotics. This result is not in agreement with the use of antibiotics as growth
980 promoters in farm animals, but the relative lack of published data on chicken
981 performance limits knowledge of the actual effects of antibiotics on animal performance
982 (Kumar et al., 2018; Broom, 2018; [Plata et al., 2022](#)). Their effects also result from their
983 interaction with the microbiota and the variables chosen in the experimental studies.

989 The effects observed in farms are dependent on the sanitary conditions present, which
990 are different from the much more controlled sanitary conditions in the experimental
991 studies and may contribute to different effects of treatment with antibiotics.

992 **Growth period**

993 An interaction between the effect of hatching conditions and chicken sex was observed
994 on BW after the challenge on D27. In males, the OFH chicken group was the heaviest
995 compared to the other groups at D34 but not at D56. These results are consistent with
996 a previous study that observed the beneficial effects of OFH on BW only until D21 (de
997 Jong et al., 2020), and not until slaughter time, as reported in various studies when
998 post-hatching feed deprivation time was at least 36 h (de Jong et al., 2017). This may
999 reflect late compensatory growth in CH chickens that have feed deprivation after
1000 hatching. Indeed, weight gain between CH and OFH chickens was no longer different
1001 from D19 for females, and from D34 for males. Alternatively, this may also be a result
1002 of the response to the challenge experienced by the chickens at D27, including
1003 transport, exposure to low temperature, transient feed deprivation, vaccination and a
1004 change to a higher rearing density, ~~but in fact there is no ultimate positive impact of~~
1005 OFH on BW at slaughter time. Moreover, in our conditions, the presence of hens
1006 eventually negatively impacted male chicken BW, but only for CH chickens at D56. In
1007 females, there was no effect of hatching conditions on the BW at D34 and D56, and
1008 the presence of hens eventually had a positive impact on OFH female chicken BW.
1009 These results were unexpected, but it is known that early stress induces sex-specific,
1010 immediate and life-long effects on the stress response, behaviour, sex hormones, and
1011 hypothalamic and blood gene expression in chickens (Madison et al., 2008; Elfving et
1012 al., 2015; Foury et al., 2020), with the males being more reactive than the females. The

a supprimé: but the

a supprimé: is that

1015 results observed in this study raise questions about the consequences of hatching
1016 conditions in the presence of a hen according to the sex of the chicks. It can be
1017 assumed that male chicks developed more fear and stress responses than females
1018 when placed in the presence of a hen, and this had negative effects on their growth
1019 until slaughter age for CH chicks. For male OFH chicks, in which the effect of hen
1020 presence on their growth was only observed during the growth phase, the
1021 communication between hens and embryonated eggs before hatching (Edgard et al.
1022 2016) and with chicks at hatching that may have a more limited effect on their growth,
1023 This could even have had negative consequences on hatchability and mortality rates,
1024 but the sex of the chicks was not recorded at that time. The presence of hens with the
1025 female OFH chicks did not affect their performance and even had a beneficial effect
1026 on their growth at slaughter age. These differences observed between treatments and
1027 chick sexes for performance are not likely explained by a difference in proximity
1028 between hens and chicks, which was low in this experiment.

1029 **Health and Robustness**

1030 There were no effects of hatching conditions on health parameters (parasitic load,
1031 clinical signs, rate of mortality), even after exposure of chickens during their growth
1032 phase to an environmental and vaccine challenge. One limitation of the experiment is
1033 that it does not reflect the farm environment which may include an accumulation of
1034 stressors in a more complex health environment. An infectious challenge could test the
1035 potential benefits of these rearing conditions. However, the challenge used in this study
1036 could have accentuated the differences in the effects of hatching conditions on
1037 performance parameters between males and females, but we did not perform the
1038 unchallenged rearing conditions to assert this. The implantation of adult microbiota into

a supprimé: rearing

a supprimé: , particularly in terms of health

a supprimé: is

1048 the chick digestive system by the presence of hens should be nevertheless beneficial
1049 for the maturation of the chick microbiota and gut immune system and still needs to be
1050 assessed.

1051 Altogether, on-farm hatching of certified broilers was a hatching system at least
1052 equivalent to the hatchery hatching system, in this study. The possibility of adding the
1053 presence of a hen at chick start-up remains tricky. The health status of the hens was
1054 controlled to ensure that no pathogens were transmitted to the chicks. However, the
1055 presence of hens, categorised according to their behaviour, revealed deleterious
1056 effects on hatching rate, the appearance quality score and hatching mortality. So, the
1057 health status and behaviour of the hens are essential to ensure the health status and
1058 welfare of the chicks. Moreover, the effects of the hens' presence at hatching and
1059 during the chick start-up phase on performance interacted with the hatching condition
1060 and the sex of the chickens. To better study hen-egg/chick interaction, the sex effect
1061 could be better characterized by in ovo sexing. Further studies should be done to
1062 assess the effects of these hatching and chick-starting conditions, in the presence or
1063 absence of hens, on the implantation and maturation of the chicks' gut microbiota and
1064 mucosal immunity. New devices enabling interactions between hens and chicks should
1065 also be tested.

1067 **Ethics approval**

1068 All experimental procedures were approved by the Ethics Committee COMETHEA
1069 POITOU-CHARENTES n°84 (APAFIS#24474-2020021816237418 v3) and carried out
1070 following current European legislation (EU Directive 2010/63/EU).

1071 **Author contributions**

1081 LAG, AB, CS, KG and AC designed the study with the help of CB. LAG, CB, AC and
1082 CS performed the experiment with the technical help of SC for the organisation of the
1083 experiment and AH for parasitic analyses. CB and LR collected the performance and
1084 health parameters. LAG analysed data with the help of AB and CB for the behaviour
1085 data. LAG, AB and CB wrote the paper with the help of KG and AC. All the authors
1086 reviewed and approved the manuscript.
